### Summary

---

Injection of CO<sub>2</sub> in subsurface reservoirs may cause overburden deformation and CO<sub>2</sub> leakage. The aim of this study is to apply technologies for detection and monitoring of CO<sub>2</sub> leakage and deformation above the injection reservoirs. The examples of this study include data from the Vestnesa Ridge natural seep site, the Snøhvit gas field and CO<sub>2</sub> storage site region, and the Gemini North gas reservoir. Reprocessing of existing 3D high-resolution seismic data allows resolving features with a vertical and lateral resolution down to c. 1 m and c. 5 m respectively. The current acquisition systems could be modified to image structures down to one meter in both the vertical and horizontal directions. We suggest a monitoring workflow that includes baseline and time-lapse acquisition of high-resolution 3D seismic data, integrated with geochemical, geophysical, and geotechnical seabed core and water-column measurements. The outcome of such a workflow can deliver reliable quantitative property volumes of the subsurface and will be able to image meter-sized anomalies of fluid leakage and deformation in the overburden.

**Figure 4** Integrated approach for the monitoring of CO<sub>2</sub> leakage. The use of high-resolution 3D seismic data allows to image structures and fluid anomalies in the shallow subsurface with a meter-size resolution. The seismic data were collected in 2014, and the exploration well 7325/4-1 was drilled in 2017. MSGL: Mega-scale glacial lineations.
